

HS651 Risk Determination of Human Biological Material – Guideline

Introduction

How should the appropriate Risk Group of human biological agents be identified? The identification of the risks is necessary in order to identify and implement appropriate controls.

Contents

1. Scope	1
2. Human materials used for teaching purposes	1
3. Human materials used for research purposes	2
4. Establishing the risk	2
4.1. AS/NZS 2243.3 Paragraph 5.3.6 Work practices (c):	2
5. Commercially supplied products	3
6. Non-commercial supplies	4
7. Vaccination	5
8. Disposal	5
9. Infection notification	5

1. Scope

The materials include established/establishing human cell lines, handling unfixed human blood, blood components and body tissues, clinical and diagnostic specimens and the risks are irrespective of the source of the materials. Work shall only be undertaken after a risk assessment of the work has been conducted and it has been demonstrated that any hazards are appropriately controlled.

2. Human materials used for teaching purposes

The requirement for a risk assessment for the biomaterials also applies to teaching, but only during class preparation, where larger volumes are being divided into the small (~5ml) tubes that will be taken into the classroom. All class participants should wear eye protection while these materials are in use in the room.

The use of human materials for teaching purposes does not require any HREC approval unless the material is to be stored or is intended for later research. HREC approval is necessary before taking tissues directly from human donors at a hospital or in the laboratory, for use as teaching materials.

The use of human materials for teaching purposes needs approval from the Head of School. This might be through a local committee convened for the purpose of approving such use and that takes into consideration safety controls described in this document. The UNSW Biosafety Coordinator can also be contacted for assistance.

All human and animal tissues and fluids should be considered potentially infectious. Although only very small quantities are being handled in classes, all participants and demonstrators in classes where these are handled should wear eye protection to shield the eyes from possible splashes with material.

3. Human materials used for research purposes

HREC approval is required for the use of all human biospecimens for research purposes. The source of the specimens can include voluntary donation, material taken for clinical purposes, plus material collected post-mortem (after death).

Irrespective of the source, HREC approval must be obtained for the research in order to confirm that the work itself is ethical. HREC approval is also necessary before taking tissues directly from human donors at a hospital or in the laboratory.

Human biospecimens are commonly collected, sorted and distributed by researchers, biobanks, blood banks, clinical pathology services, health care providers, research institutes, commercial entities, such as pharmaceutical and biotechnology companies and could be specimens sourced from other researchers and collaborators.

Research involving human embryos and gametes, including derivation of human embryonic stem cell lines, requires HREC approval which forms part of a licence application to the Embryo Research Licensing Committee.

4. Establishing the risk

4.1. AS/NZS 2243.3 Paragraph 5.3.6 Work practices (c):

“When handling human blood, serum, other body fluids and substances that are visibly contaminated with blood, appropriate publications shall be consulted, such as the Australian guidelines for the prevention and control of infection in health care. The risk extends to human sera and derivatives used as control reagents (both positive and negative) in diagnostic and other procedures.

NOTE: Although existing test methods for viruses are sensitive, they do not entirely preclude the possibility of viral contamination. The fact that a serum sample is used as a negative control for some particular test does not necessarily mean that it is free of viruses.”

Unless they meet one of two exceptions, all unfixed human blood, blood components, tissues, primary human cell lines and strains, and clinical and diagnostic specimens, shall be considered Risk Group 2, handled in a PC2 facility, and require Risk Group 2 practices (or precautions) as described below.

The two exceptions are if:

- the samples are accompanied by written confirmation from the supplier that the product contains no known human pathogens; or
- a higher Risk Group is indicated in the accompanying documentation and clinical notes.

Such biospecimens *will include*:

- Established human or other animal cell lines which are known to be or likely to be infected/contaminated with human microbes or agents, particularly those classed as blood-borne pathogens, especially hepatitis viruses and human immunodeficiency viruses. They must be considered Risk Group 2 as a minimum.
- All human whole-blood, blood products, urine, saliva, body fluids and faeces may contain multiple types of infectious microorganisms and must be regarded as potentially containing human pathogens that could be a respiratory, mucosal, and/or sharps injury risk.

Risk Group 2 work practices include:

- Any work where aerosols might be generated must be carried out in a BSC or an appropriate centrifuge such as a bio centrifuge (with buckets that have fully sealed lids) and not on the open bench.
- All manipulations of any of these tissues and substances should be done in a BSC class II. In particular:
 - Load and unload the centrifuge buckets or rotors in a BSC; and
 - Decontaminate outer surfaces of all items before removal from the BSC, including your hands.
- Avoid the use of any items that could penetrate the skin to help prevent sharps injuries.
- Pay attention to protecting the mucosal membranes, especially the eyes, including when working at the BSC.
- Double-contain and decontaminate the outer container surfaces for transport out of the facility.
- Dispose of biological waste into the appropriate waste-stream.

- Wear PPE which includes a rear-fastening laboratory gown, appropriate safety eyewear, fully enclosed shoes, and gloves of appropriate material (with the glove cuff over the top of the gown cuff to protect the wrists).
- If gloves have been splashed, discard them into the biological waste, wash hands and re-glove.
- Remove gloves in the BSC.
- Clean the work area before work begins and once work has finished (or at the end of the day).
- Wash hands thoroughly immediately before leaving the facility.

Additional precautions include:

- Using safer devices such as:
 - plastic rather than glass capillary and blood collection tubes; and
 - retractable or self-sheathing devices.
- Avoiding the use of any sharp instruments and devices.
- Double-gloving.
- Double containing items while moving around the facility is also recommended as it will help minimise the extent of a spill.

If the pathogen-free status is not known, it should be assumed that pathogens are present. Consideration should also be given to the fact that many viruses have been confirmed to be human carcinogens (See Appendix B for examples).

At the very least, implementing the basic infection control principle will help to minimise the risk of contaminating of the work of others.

The UNSW *HS329 Risk Management Procedure* needs to be followed to identify the hazards, assess the risks associated with the hazards and to control these risks. A safe work procedure must be written to provide a step-by-step description of the process, incorporating all of the identified controls, including containment level and any vaccinations that may be relevant.

Characterization of (human) cells - in order that cells can be included in or excluded from compliance with Risk Group 2 precautions, the cell lines or 'strains' would need to be screened for human pathogens, especially

- viruses characterized as blood-borne pathogens by the US Labor Department Standard. (Pathogens including human immunodeficiency viruses, hepatitis viruses or Epstein-Barr virus) and
- if the cells are capable of propagating such viruses.

Any documentation accompanying commercial and non-commercial deliveries should be kept as evidence to support your risk assessment. Most commercial cell lines are screened for human mycoplasmas and are free of bacterial and mycotic contaminants but not necessarily free of blood-borne pathogens.

Where testing occurs, it may include antigenic screening for viral or agent markers, co-cultivation with various indicator cells that allow contaminants to grow, or using molecular technology (polymerase chain reaction or nucleic acid hybridization) to identify latent viruses capable of infecting humans such as Herpes viruses (e.g., Epstein Barr virus), or papilloma members of the Papovavirus group, etc.

Human cell lines either purchased commercially or from other sources may be handled as Risk Group 1 as noted in AS/NZS 2243.3 only if:

- they have accompanying documentation stating that they are tested to be free of human blood-borne pathogens **and**
- they have been protected from contamination at the workplace by the researchers.

All other human cell lines, particularly primary cell lines, and human cell strains must be handled as potential biohazards (minimum Risk Group 2).

5. Commercially supplied products

Unless there is written confirmation that the product is free from known human pathogens, the use of purchased human biospecimens must follow Risk Group 2 precautions as just described.

The Australian Red Cross Life Blood Service (Blood Service) is a popular source of unfixed human blood and blood components used for teaching and research at UNSW. These have been tested but it does not guarantee that their product is pathogen free. This is because although the Blood Service has a very detailed

eligibility questionnaire for its donors, and every donation is tested, the tests are only for five specific blood-borne pathogens (also known as transfusion-transmissible infectious diseases). These are:

- HIV (1 & 2);
- hepatitis B;
- hepatitis C;
- human T-cell lymphotropic virus (HTLV 1 & 2); and
- syphilis.

Other tests, such as Malaria, are carried out when indicated in the questionnaire.

The Blood Service testing is confined only to this specific group of blood-borne diseases for which there are suitable high-volume tests. Note however, if someone has only very recently acquired an infection, there is a window period where the tests are not likely to pick up evidence of the disease, meaning an infection could be passed on to others through the handling of the product.

The Blood Service considers that it is impossible to reduce the risk to zero for the presence of these five pathogens, or if the blood or blood product might contain other pathogens.

There are infectious agents for which there are no routine available tests to predict or prevent the disease from being present in blood products and therefore potentially being transmitted to handlers.

These include, but are not limited to:

- Dengue virus (dengue fever).
- West Nile virus (West Nile virus infection).
- Trypanosoma cruzi (Chagas' disease).
- Parvovirus B19 (B19 viral infection); and
- Epstein-Barr virus.

There is also the possibility of bacterial contamination in Blood Service products, and although this risk is reduced by bacterial contamination screening of platelet concentrates (in addition to donor selection criteria) it is impossible to reduce this risk to zero.

Where commercially sourced supplies are not accompanied by documentation stating the material is pathogen-free (of *all* known human pathogens), researchers need to follow normal risk management processes where residual risks are identified and managed. This can include:

- assuming that pathogens might be present and therefore following normal Risk Group 2 work practices to control the potential respiratory, mucosal, skin exposure and sharp injury risk.
- assessing and rating the residual risk according to the Risk Rating Matrix and following the resulting required action.
- testing for any known blood-borne human pathogens that were not covered by the commercial entity.

6. Non-commercial supplies

All non-commercially obtained unfixed human blood, blood components, body fluids and tissues, must be regarded as at least Risk Group 2 and should be handled while following Risk Group 2 precautions, as already outlined, unless guaranteed in writing to be free of all known human pathogens.

Where specimens are accompanied by clinical notes that suggest that higher Risk Group microorganisms might be present, a higher-level physical containment facility might be required for handling the specimen or any isolates.

In-house donations

Occasionally a researcher requires tissue for part of their research, and wants to collect it (e.g., blood) from a colleague. Before this stage of the research can continue, the project supervisor must ensure that the person collecting the blood has been appropriately trained in the technique of venipuncture and will follow appropriate infection control methods. Before the sample is collected, HREC approval must also be in place to cover donor consent and also the intended use of the blood.

It is important to take into consideration the fact that the donor may be taking medication and or vitamins that could 'thin' the blood, affecting clotting time, and donors may also be infected with one or several blood borne pathogens.

Further information regarding the identification of Risk Groups and controls can be obtained from AS/NZS 2243.3, and from the UNSW Biosafety Coordinator.

7. Vaccination

Please refer to the *Immunisation Guideline: Tetanus, Hepatitis A, Hepatitis B and Q fever*.

8. Disposal

The disposal of waste must follow the *UNSW Laboratory Hazardous Waste Disposal Guideline*.

- Any biological tissues or fluids that have been either chemically fixed or chemically decontaminated must be disposed of as chemical waste.
- Unfixed or autoclaved biological materials are disposed of as biological waste.
- Biological materials that are contaminated with cytotoxic substances must be disposed of as cytotoxic waste.

9. Infection notification

SafeWork-reportable incident

This is an infection attributed to working with a microorganism, human blood or body substances, animals, animal parts or animal waste products. Immediately on learning that a person has become infected, the incident must be reported to the Head of School/ Research group or the facility manager, and also to the Faculty WHS Business Partner/Coordinator or the WHS Unit Manager. Incidents must also be reported via the myUNSW online reporting system, irrespective of whether the occasion involved teaching or research.

Appendix A: from AS/NZS2243.3:2010 paragraph 2.1.2 Risk Assessment

Research, teaching or operational work with biohazards shall only be undertaken after a risk assessment of the work has been conducted and it has been demonstrated that any hazards are controlled. This process shall be documented and regularly reviewed to ensure its ongoing validity. Review shall be undertaken whenever a change to the parameters of the original risk assessment is planned.

The risk assessment shall be done prior to commencement of any work to determine the appropriate type and level of containment facility. The risk assessment should include consideration of the following:

- a) The microorganisms involved, their presence or absence in Australia and New Zealand, their source, Risk Group, volume, concentration, mode of transmission, host range, minimum infectious dose, vectors and the nature of the proposed work.
- b) The process and equipment to be used.
- c) Storage requirements and safe handling between work areas and storage areas.
- d) The containment performance of the facility construction, including the seal quality, air pressure and directional control mechanisms, treatment and filtration of air leaving the facility and emergency backup systems, where applicable.
- e) The suitability of containment equipment such as biological safety cabinets, for the intended work.
- f) Provisions for handling, decontamination, and disposal of potentially contaminated waste, including liquid waste from drains.
- g) The availability and suitability of PPE for the intended work.
- h) The training and experience of the staff/workers with the particular microorganisms proposed for the work.
- i) Any health considerations for staff e.g., vaccinations, medical monitoring.
- j) The capability to deal with a spill, such as by facility gaseous decontamination.

All risk assessments that involve biological systems are subject to a level of uncertainty due to a lack of experimental evidence. The level of uncertainty should be considered when conducting the risk assessment.

Appendix B: Examples of pathogens listed as Group 1 human carcinogens

- Human T-cell lymphotropic virus type 1
- Epstein-Barr Virus (EBV)
- Hepatitis B virus (HBV) chronic infections
- Hepatitis C virus (HCV) chronic infections
- Human immunodeficiency virus (HIV) type 1
- Human papilloma virus (HPV) – twelve of the types identified as group 1
- *Helicobacter pylori* (may be in faecal & gut samples)

- *Opisthorchis viverrini* (may be in faecal & gut samples)

Source: IARC Monographs on the evaluation of carcinogenic risks to humans (WHO) 2014

Appendix C: Definitions and terminology

Biocentrifuge – often referred to as a centrifuge, but not to be confused with ordinary centrifuge.

Biocentrifuges are to be used when spinning infectious materials and must have at least sealed buckets or sealed rotors, to contain aerosols & spills. No centrifuge is to be used in a BSC class I or II unless the cabinet has been tested and passed the containment test with the centrifuge in situ and in full operation. Where possible, buckets and rotors must be loaded and unloaded in a BSC.

Biosafety cabinet (BSC) – HEPA-filtered local exhaust ventilation cabinet used to protect the operator from hazardous biological agents, particularly when working with microorganisms transmissible via the respiratory route. The two main classes of cabinet are:

- Class I protects the worker and others in the laboratory; and
- Class II protects the worker, the work and others in the laboratory.

Biospecimen (also called specimens or samples) – in this document refers specifically to any biological material obtained from a person, including tissues, blood, urine, sputum, wastes and any component or derivative from these, and includes cell lines and strains. It does not include non-human biological material that can be found on or in a person, such as microorganisms.

Blood-borne pathogen – microorganisms in the blood or other body fluids that can cause illness and disease in people. These microorganisms are mostly viruses but can be other types of pathogens and can be transmitted through handling contaminated blood and body fluids by:

- An accidental puncture by a sharp object (e.g., needles, scalpels, or broken glass) that has been contaminated with the pathogen.
- Open cuts or skin abrasions coming in contact with contaminated blood or body fluids.
- Contact with the mucous membranes of the eyes, mouth, or nose.
- Inhalation of contaminated aerosols;
- Handling unfixed human blood, blood products and tissues;

Cell LINE – a permanently established *in-vitro* cell culture that has been **immortalised**, transformed to be able to proliferate indefinitely if given appropriate fresh medium, space and conditions.

- Human cell line** - an *in-vitro* or animal passaged (eg nude mouse) permanently established culture of human cells that fulfill traditional requirements of a cell line designation, being transformed or immortalised cells. They may no longer behave like the original cells. An example is the HeLa cell line made up of cervical carcinoma cells taken from a patient in 1951.
- Primary human cell lines:** Those directly cultured from their source organ tissue or blood cells. They are often within approximately 4-8 passages, or less than 72 hours old. These cells come directly from the source on the human body, so for a short period they can give extremely accurate information about the cells in-vivo and give relevant information regarding the living systems.

Cell STRAIN – cells propagated *in-vitro* from primary culture, explants of tissue or body fluids and which are not immortalised. They are unable to proliferate indefinitely and therefore have a finite lifetime (non-transformed) in tissue culture for 20-70 passages.

- Human cell STRAINS** – non-transformed cells propagated *in-vitro* from primary explants of human tissue or human body fluids. They have not been immortalised and therefore have a finite lifetime in tissue culture, for 20-70 passages.

Epstein-Barr virus (EBV) - a blood-borne herpes virus. In a small number of cases, infection can lead to malignant lymphoma.

HeLa cells - human cervical carcinoma cells.

Human Research Ethics Committee (HREC) - the UNSW committee overseeing the ethics relating to human research, and includes the use of human blood, blood components and body tissues for research purposes at UNSW, irrespective of the source.

Immortalised cells - those that have been transformed by spontaneous mutation or by natural or laboratory infection with an immortalising agent such as Epstein-Barr virus (EBV) to enable indefinite proliferation. It

is more likely that there is only one cell type remaining in the culture, and the cell line may no longer behave like the original primary cell line.

In-vitro – a procedure that is performed not in a living organism, but in a controlled environment outside the body, such as in a test tube or petri-dish.

In-vivo - 'in the living'. A procedure that is performed in a living organism.

Physical containment level 2 (PC2) – the specific containment and behavioral requirements, as described in AS/NZS2243.3. This is the minimum containment level required for handling Risk Group 2 biological agents, most cell lines/strains, and unfixed human blood, blood components and tissues.

PPE – Personal protective equipment (includes clothing).

Risk Group – the classification of microorganisms that are infectious for humans and animals, based on the pathogenicity of the agent, the mode of transmission, host range of agent, and the availability of effective preventative measures and treatments. Described in AS/NZS2243.3:2010, paragraph 3.2.2 (human and animal pathogens) as Risk Group 1 to 4, with 1 being of lowest risk (there being no human pathogens) and 4 being highest risk, most are listed in the tables in AS/NZS2243.3.

Sharps injury (also known as needlestick or stick injury) – any penetrating skin injury by a sharp object or device that is or might be contaminated with an infectious agent, and in particular a pathogen with the route of exposure via the blood stream, such as a blood-borne virus. Sharp objects include needles (syringe and suture), scalpel blades, wires, trocars, auto lancets, stitch cutters, fine-tipped scissors and forceps, and broken glassware.
